

Case Study 1: XML-Based Configuration

Case Study Title: Hospital Management System

Scenario:

A hospital wants a simple system to manage patient information, appointments, and billing. You need to implement these features using Spring's XML-based configuration.

Folder Structure:

```
hospital-management-xml/  
├── src/  
│   ├── main/  
│   │   ├── java/  
│   │   │   ├── com/example/hospital/  
│   │   │   │   ├── Patient.java  
│   │   │   │   ├── Appointment.java  
│   │   │   │   ├── Billing.java  
│   │   │   │   ├── HospitalService.java  
│   │   │   ├── resources/  
│   │   │   └── applicationContext.xml  
│   └── pom.xml
```

POJO Classes:

1. Patient.java

- registerPatient(): Register a new patient
- getPatientDetails(): View details

```
package com.example.hospital;  
  
public class Patient {  
    private String name;  
    private int age;  
  
    public void setName(String name) {  
        this.name = name;  
    }  
    public void setAge(int age) {  
        this.age = age;  
    }  
  
    public void registerPatient() {  
        System.out.println(" Patient registered: " + name + ", Age: " + age);  
    }  
  
    public void getPatientDetails() {  
        System.out.println(" Patient Details: " + name + " (Age: " + age + ")");  
    }  
}
```

2. Appointment.java

- bookAppointment(): Book appointment
- cancelAppointment(): Cancel it

```
package com.example.hospital;
```

```
public class Appointment {  
    public void bookAppointment() {  
        System.out.println("Appointment booked successfully!");  
    }  
  
    public void cancelAppointment() {  
        System.out.println(" Appointment cancelled!");  
    }  
}
```

3. Billing.java

- generateBill(): Generate invoice
- sendBill(): Email invoice

```
package com.example.hospital;
```

```
public class Billing {  
    public void generateBill() {  
        System.out.println(" Bill generated successfully!");  
    }  
  
    public void sendBill() {  
        System.out.println(" Bill sent to patient's email!");  
    }  
}
```

//HospitalService.java

```
package com.example.hospital;
```

```
public class HospitalService {  
    private Patient patient;  
    private Appointment appointment;  
    private Billing billing;  
  
    public void setPatient(Patient patient) {  
        this.patient = patient;  
    }  
    public void setAppointment(Appointment appointment) {  
        this.appointment = appointment;  
    }  
}
```

```

    }
    public void setBilling(Billing billing) {
        this.billing = billing;
    }

    public void manageHospital() {
        patient.registerPatient();
        patient.getPatientDetails();
        appointment.bookAppointment();
        billing.generateBill();
        billing.sendBill();
    }
}

```

//applicationContext.xml

```

<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd">

    <!-- Patient Bean -->
    <bean id="patient" class="com.example.hospital.Patient">
        <property name="name" value="John Doe"/>
        <property name="age" value="30"/>
    </bean>

    <!-- Appointment Bean -->
    <bean id="appointment" class="com.example.hospital.Appointment"/>

    <!-- Billing Bean -->
    <bean id="billing" class="com.example.hospital.Billing"/>

    <!-- HospitalService Bean (Dependency Injection) -->
    <bean id="hospitalService" class="com.example.hospital.HospitalService">
        <property name="patient" ref="patient"/>
        <property name="appointment" ref="appointment"/>
        <property name="billing" ref="billing"/>
    </bean>
</beans>

```

//MainApp.java

```

package com.example.hospital;
import org.springframework.context.ApplicationContext;
import org.springframework.context.support.ClassPathXmlApplicationContext;

```

```

public class MainApp {
    public static void main(String[] args) {
        ApplicationContext context = new ClassPathXmlApplicationContext("applicationContext.xml");

        HospitalService hospitalService = context.getBean("hospitalService", HospitalService.class);
        hospitalService.manageHospital();
    }
}

```

Key Learning:

- Use of XML to wire beans.
- applicationContext.xml manages object creation and dependencies.
- Beans injected using <bean> and <property> tags.

Case Study 2: Java-Based Configuration

Case Study Title: E-Commerce Order Processing

Scenario:

An e-commerce application handles product orders, payments, and inventory. We implement the service using Spring's Java configuration (@Configuration, @Bean).

Folder Structure:

```

ecommerce-java-config/
├── src/
│   ├── main/
│   └── java/
│       ├── com/example/ecommerce/
│       │   ├── Product.java
│       │   ├── Order.java
│       │   ├── Payment.java
│       │   ├── EcommerceService.java
│       │   └── AppConfig.java
│       └── pom.xml

```

POJO Classes:

//pom.xml

```

<project xmlns="http://maven.apache.org/POM/4.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0
        http://maven.apache.org/xsd/maven-4.0.0.xsd">

```

```

    <modelVersion>4.0.0</modelVersion>
    <groupId>com.example</groupId>

```

```

<artifactId>ecommerce-java-config</artifactId>
<version>1.0-SNAPSHOT</version>

<properties>
  <maven.compiler.source>17</maven.compiler.source>
  <maven.compiler.target>17</maven.compiler.target>
</properties>

<dependencies>
  <!-- Spring Core -->
  <dependency>
    <groupId>org.springframework</groupId>
    <artifactId>spring-core</artifactId>
    <version>5.3.39</version>
  </dependency>

  <!-- Spring Context (Java-based config support) -->
  <dependency>
    <groupId>org.springframework</groupId>
    <artifactId>spring-context</artifactId>
    <version>5.3.39</version>
  </dependency>
</dependencies>
</project>

```

1. Product.java

- addProduct(), listProducts()

//Product.java

```

package com.example.ecommerce;
import java.util.ArrayList;
import java.util.List;

public class Product {
  private List<String> products = new ArrayList<>();

  public void addProduct(String productName) {
    products.add(productName);
    System.out.println("Product added: " + productName);
  }

  public void listProducts() {
    System.out.println("Available Products:");
    for (String p : products) {
      System.out.println(" - " + p);
    }
  }
}

```

```
}
```

2. Order.java

- createOrder(), cancelOrder()

```
package com.example.ecommerce;
public class Order {
    public void createOrder(String product) {
        System.out.println("Order created for product: " + product);
    }

    public void cancelOrder(String product) {
        System.out.println("Order cancelled for product: " + product);
    }
}
```

3. Payment.java

- processPayment(), refundPayment()

```
package com.example.ecommerce;
public class Payment {
    public void processPayment(double amount) {
        System.out.println("Payment processed: $" + amount);
    }

    public void refundPayment(double amount) {
        System.out.println("Payment refunded: $" + amount);
    }
}
```

//EcommerceService.java

```
package com.example.ecommerce;
public class EcommerceService {
    private Product product;
    private Order order;
    private Payment payment;

    public EcommerceService(Product product, Order order, Payment payment) {
        this.product = product;
        this.order = order;
        this.payment = payment;
    }

    public void runEcommerceFlow() {
        product.addProduct("Laptop");
        product.addProduct("Smartphone");
    }
}
```

```
        product.listProducts();
        order.createOrder('Laptop');
        payment.processPayment(1500.00);
        payment.refundPayment(1500.00);
        order.cancelOrder('Laptop');
    }
}
```

//AppConfig.java

```
package com.example.ecommerce;
import org.springframework.context.annotation.Bean;
import org.springframework.context.annotation.Configuration;
```

```
@Configuration
public class AppConfig {

    @Bean
    public Product product() {
        return new Product();
    }
    @Bean
    public Order order() {
        return new Order();
    }
    @Bean
    public Payment payment() {
        return new Payment();
    }
    @Bean
    public EcommerceService ecommerceService() {
        return new EcommerceService(product(), order(), payment());
    }
}
```

//MainApp.java

```
package com.example.ecommerce;
import org.springframework.context.ApplicationContext;
import org.springframework.context.annotation.AnnotationConfigApplicationContext;

public class MainApp {
    public static void main(String[] args) {
        ApplicationContext context = new AnnotationConfigApplicationContext(AppConfig.class);
        EcommerceService service = context.getBean(EcommerceService.class);
        service.runEcommerceFlow();
    }
}
```

Key Learning:

- Uses @Configuration and @Bean to define dependencies.
- No need for XML.
- AnnotationConfigApplicationContext is used instead of ClassPathXmlApplicationContext.

Case Study 3: Annotation-Based Configuration

Case Study Title: Library Management System

Scenario:

A small community library wants a system to manage books, members, and loans. You implement this using annotation-based Spring (@Component, @Autowired).

Folder Structure:

library-annotation-config/

POJO Classes:

//pom.xml

```
<project xmlns="http://maven.apache.org/POM/4.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0
    http://maven.apache.org/xsd/maven-4.0.0.xsd">
```

```
  <modelVersion>4.0.0</modelVersion>
  <groupId>com.example</groupId>
  <artifactId>library-annotation-config</artifactId>
  <version>1.0-SNAPSHOT</version>
```

```
  <properties>
    <maven.compiler.source>17</maven.compiler.source>
    <maven.compiler.target>17</maven.compiler.target>
  </properties>
```

```
  <dependencies>
    <!-- Spring Core -->
```

```

<dependency>
  <groupId>org.springframework</groupId>
  <artifactId>spring-core</artifactId>
  <version>5.3.39</version>
</dependency>

<!-- Spring Context (Annotation-based config support) -->
<dependency>
  <groupId>org.springframework</groupId>
  <artifactId>spring-context</artifactId>
  <version>5.3.39</version>
</dependency>
</dependencies>
</project>

```

1. Book.java

◦ addBook(), searchBook()

```

package com.example.library;
import org.springframework.stereotype.Component;

```

```

@Component
public class Book {
    public void addBook(String title) {
        System.out.println("    Book added: " + title);
    }

    public void searchBook(String title) {
        System.out.println("    Searching for book: " + title);
    }
}

```

2. Member.java

◦ registerMember(), viewMembers()

```

package com.example.library;
import org.springframework.stereotype.Component;

```

```

import java.util.ArrayList;
import java.util.List;

```

```

@Component
public class Member {
    private List<String> members = new ArrayList<>();

    public void registerMember(String name) {
        members.add(name);
    }
}

```

```

        System.out.println("✔ Member registered: " + name);
    }

    public void viewMembers() {
        System.out.println("    Registered Members:");
        for (String m : members) {
            System.out.println(" - " + m);
        }
    }
}

```

3. Loan.java

◦ issueBook(), returnBook()

```

package com.example.library;
import org.springframework.stereotype.Component;

@Component
public class Loan {
    public void issueBook(String title, String member) {
        System.out.println("    Book issued: " + title + " to " + member);
    }

    public void returnBook(String title, String member) {
        System.out.println("    Book returned: " + title + " by " + member);
    }
}

```

LibraryService.java

```

package com.example.library;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.stereotype.Component;

@Component
public class LibraryService {

    @Autowired
    private Book book;

    @Autowired
    private Member member;

    @Autowired
    private Loan loan;

    public void libraryOperations() {
        // Step 1: Add and Search Book
    }
}

```

```

book.addBook("Java Programming");
book.addBook("Spring Framework");
book.searchBook("Java Programming");

// Step 2: Register and View Members
member.registerMember("Sravani");
member.registerMember("John");
member.viewMembers();

// Step 3: Issue and Return Books
loan.issueBook("Java Programming", "Sravani");
loan.returnBook("Java Programming", "Sravani");
}
}

```

MainApp.java

```

package com.example.library;
import org.springframework.context.ApplicationContext;
import org.springframework.context.annotation.AnnotationConfigApplicationContext;
import org.springframework.context.annotation.ComponentScan;
import org.springframework.context.annotation.Configuration;

@Configuration
@ComponentScan(basePackages = "com.example.library")
public class MainApp {
    public static void main(String[] args) {
        ApplicationContext context = new AnnotationConfigApplicationContext(MainApp.class);

        LibraryService libraryService = context.getBean(LibraryService.class);
        libraryService.libraryOperations();
    }
}

```
